

Five Ways Attackers Get to Databases

Ransomware

Ransomware attacks are increasingly targeting database programs such as MySQL, MongoDB & Hadoop.

Privilege Abuse

Privilege abuse occurs when the privileges associated with user accounts are used inappropriately or fraudulently.

Misconfigurations

Misconfigured databases have been a major problem across all sectors, especially in the health care sector and make them vulnerable to attacks.

Malicious Insider

Insider threats come from people within the organization. For example, rogue employees of a global health insurer advertised its database for sale on the dark web, potentially affecting a million customers.

Rise in Vulnerabilities

Vulnerabilities are increasing at an unrelenting pace with dire consequences for organizations.
